

## OBSERVER DATA HELD BY THE OCEANIC FISHERIES PROGRAMME COVERING TUNA FISHERY BYCATCHES IN THE WESTERN AND CENTRAL PACIFIC OCEAN

Tim Lawson

## INTRODUCTION

At the thirteenth meeting of the Standing Committee on Tuna and Bilfish, which was held from 5 to 12 July 2000 at SPC headquarters, a directive was provided to the Statistics Working Group to document the data that are available to estimate bycatches in the tuna fisheries of the western and central Pacific Ocean (Anon 2001). This document presents a summary of the longline, pole-andline and purse-seine observer data held by the SPC Oceanic Fisheries Programme in April 2001 that can be used to estimate bycatches. The observer data are summarised with regard to the sources of data, the species covered, the school association (for pole-and-line and purse seine), the proportion of the observed catch not identified to the species level, the discard rate, the condition of discards (for longline), geographic coverage, temporal coverage, and the coverage by fishing nation.

## LONGLINE OBSERVER DATA

## Sources of Data

The longline observer data held by the OFP were obtained from eight observer programmes, i.e. the national programmes of Australia (1987-1997), Federated States of Micronesia (1992-1999), Marshall Islands (1995, 1997), New Zealand (1987-1999), Palau (1999), Papua New Guinea (1999) and Solomon Islands (1996, 1998-1999), and the SPC regional programme (1992-2000). The SPC programme covered longliners operating in the waters of American Samoa, Cook Islands, Fiji, Federated States of Micronesia, French Polynesia, Kiribati, Marshall Islands, New Caledonia, Papua New Guinea, Palau, Samoa, Solomon Islands and Tonga. The Australian and New Zealand data account for 42.6 and 38.2 percent of the data respectively, while the other national programmes account for 9.9 percent and the SPC programme accounts for 9.3 percent (Table 1).

There were 10,244 longline sets made in the WCPO, from 1987 to 2000, that were covered by observer data held by the OFP. However, 714 sets could not be used because bycatches were not monitored by the observer during the trip. An additional 66 sets made by French Polynesian longliners outside the WCPO, but near its eastern boundary, were included. The total number of sets available for the analysis of bycatch was therefore 9,596 .

There were 341 sets for which the number of hooks observed was unknown, primarily covering Japanese longliners in the AFZ during 1987-1992. For these sets, the number of hooks observed has been estimated from the average number of hooks observed for other sets from the same source of observer data and for the same vessel nationality. If there were no sets in the same year that could used to estimate the average number of hooks observed per set, then a range of years was used.

## Species Covered

Table 2 presents the number of individuals from the following species groups that were observed in the catch: tunas, tuna-like species, billfish, sharks and rays, other fish, cephalopods, marine reptiles, birds, and marine mammals. ${ }^{1}$ The most numerous species observed in the catch was albacore tuna (Thunnus alalunga, 129,539 observed), followed by blue shark (Prionace glauca, 98,066 observed), southern bluefin tuna (Thunnus maccoyi, 56,761 observed), yellowfin tuna (Thunnus albacares, 50,843 observed) and bigeye tuna (Thunnus obesus, 20,540 observed).

[^0]Table 2 represents the species and species groups observed in all observer programmes. However, the relative proportions of species observed depends on the geographic area. This is apparent when the number of individuals observed is broken down by observer programme. For example, 66.4 and 33.6 percent of southern blue tuna are covered in the observer data provided by Australia and New Zealand, whereas only one southern bluefin was observed in the other national programmes and no southern bluefin were observed by SPC observers. Table 3 presents the number of individuals observed broken down by species groups and observer programmes. The following points are of intrerest:
> In the Australian programme, tunas represent 71.8 percent of the catch, whereas sharks and rays and other fish represent 15.3 and 7.6 percent respectively. There were only 11 birds and no marine reptiles or marine mammals observed. It is strongly suspected that the small number of birds and the lack of marine reptiles and marine mammals in the data provided by Australia may be due to incomplete data provided to the OFP; the Australian Fisheries Management Authority has been contacted in this regard.
> In the New Zealand programme, tunas represent 29.3 percent of the catch, whereas sharks and rays and other fish represent 43.7 and 21.4 percent respectively. Almost all birds, 98.7 percent, and marine mammals, 96.5 percent, were observed in the New Zealand programme. There were only 5 marine reptiles observed.
$>$ In the other national programmes and the SPC programme, tunas represent 56.9 percent of the catch, whereas sharks and rays and other fish represent 22.3 and 10.9 percent respectively. Almost all marine reptiles, 95.6 percent, were observed in the other programmes and only 8 birds and 12 marine mammals were observed.

## Species Identification

Table 4 presents the percentage of observed individuals that were not identified to the species level. The percentage is low (less than 1.0 percent) for tuna, tuna-like species and billfish, whereas it is moderate for sharks and rays ( 3.6 percent), other fish ( 5.9 percent) and marine mammals (4.1 percent) and high for marine reptiles ( 42.9 percent) and birds ( 64.3 percent). Overall, 3.0 percent of observed individuals were not identified to the species level.

Most of the sharks and rays that were not identified to the species level were hammerhead sharks (Sphyrna spp.), mako sharks (Isurus spp.) and thresher sharks (Alopias spp.) that were identified to the generic level. Many of the birds that were not identified to the species level were albatross (Diomedea spp.) or petrels (Procellaria spp.).

## Discard Rate and Condition of Discards

Table 5 presents the number of fish observed, and the numbers retained and discarded, by species group. Most tunas, tuna-like species and billfish were retained, while 63.8 percent of sharks and rays and 57.0 percent of other fish were known to have been discarded. The large numbers of sharks and rays and other fish for which it is not known whether they were retained or discarded represent data from the New Zealand programme; information regarding the fate of these fish was not provided.

The life status of individuals at the time of hauling was assigned by observers in the national programmes of countries other than Australia and New Zealand, and by SPC observers, using the following codes:

- A0 Alive, not classed as A1, A2 or A3
- A1 Alive, healthy
- A2 Alive, injured or distressed
- A3 Alive but dying
- D Dead
- U unknown

Codes for the condition of discards observed in the Australian programme were similar to those listed above. However, the condition of discards observed in the New Zealand programme were assigned to only three categories: 'alive, not classed as A1, A2 or A3', 'dead' and 'unknown'.

Table 6 presents a breakdown of all discards by the condition code. Overall, 59.4 percent of discards were dead or dying, while 5.9 percent of discards were alive and healthy at the time of hauling. Discards that were alive and healthy when caught have a strong probability of survival, while those discarded dying or dead are obviously removed from the population.

However, 34.7 percent of discards were individuals for which the condition code is 'alive, not classed' or 'alive, injured' or 'unknown'. For these discards, it is uncertain whether they survived. In estimating catches and catch rates below, only discards that have a condition code of 'alive, healthy' were considered to have survived. Given that an unknown proportion of discards having a condition code of 'alive, not classed' or 'alive, injured' or 'unknown' may have survived, the catches and catch rates may be over-estimated.

The condition of discards varies among the species groups. More than half of the sharks and rays, tuna-like species, birds and billfish were dead or dying, while less than half of other fish and marine reptiles were dead or dying. Almost all marine mammals were alive, but since almost all were observed in the New Zealand programme, the life status of 90.6 percent of the discarded marine mammals was not classed as 'healthy', injured' or 'dying'. The species group with the largest proportion of discards that were alive and healthy was marine reptiles ( 25.9 percent).

## Geographic Coverage

The geographic coverage of the observed longline effort is compared to the total longline effort in the WCPO during 1987-1999 in Figures 1 and 2. The distribution of the observed longline effort is not representative of the total effort, with a disproportionately greater amount of observed effort in the waters of Australia and New Zealand and a smaller amount on the high seas, particularly in the northern and eastern areas of the WCPO.

Longline effort on the high seas in the WCPO is mainly conducted by the distant-water fleets of Japan, Korea and Taiwan. The paucity of observed effort on the high seas is the result of the fact that most observers that collected the data held by the OFP were placed onboard through opportunities provided by access agreements between foreign vessels and coastal states; hence, when the foreign vessel left the EEZ of the coastal state, the observer was usually required to disembark. The distant-water fleets have not been covered on a regular basis by observer programmes of those fishing nations; hence, almost no observer data have been collected for areas beyond the EEZs of the coastal states with which those fishing nations have had access agreements.

Figure 2 does not show observer coverage of the United States longline fleet based in Honolulu, since these data are not included in the OFP database. Approximately 5 percent of longline trips in Hawaii have been covered by observers of the National Marine Fisheries Service since February 1994.

## Temporal Coverage

The temporal distribution of observer coverage is presented in Tables 1 and 7 and Figures 3 and 4 . The total number of hooks observed reached a maximum in 1993, when coverage in the Australian programme peaked and coverage in the New Zealand programme was high. Coverage in both programmes subsequently declined. Coverage in the New Zealand programme increased considerably in 1997, which was the last year of the Australian programme. Coverage for 2000 will increase when data from the programmes of the Federated States of Micronesia and New Zealand are provided tp SPC.

Coverage as a percentage of the total catch increased from 0.01 percent in 1987 to 0.42 percent in 1997 and then declined.

## Total Coverage and Coverage by Fishing Nation

Total coverage of the catch of target species in the WCPO from 1987, the first year for which observer data are available, to 2000 is 0.18 percent (Table 7). The level of observer coverage is consistently low among fleets and years. There are only 15 fleet-years out of 223 for which coverage is greater than 1 percent and only one fleet-year for which coverage is greater than 5 percent. No observer data are held by the OFP for the longline fleets of Indonesia or the Philippines.

Table 8 compares the observed catch to the total catch of target species, for each fishing nation. The distribution of observer coverage by fishing nation is roughly similar to the distribution of the total catch, except for the fleets of Indonesia and the Philippines, for which no observer data are available, and the Korean fleet, which caught 17.8 percent of the total catch, but only 2.8 percent of the observed catch.

The largest proportion of the observed catch is for the Japanese fleet ( 67.2 percent), followed by the fleets of Taiwan ( 12.8 percent), China ( 3.6 percent), Korea ( 2.8 percent), Solomon Islands ( 2.6 percent), Papua New Guinea ( 2.1 percent), French Polynesia ( 2.0 percent), Tonga ( 1.6 percent), New Caledonia (1.4 percent) and Fiji Islands (1.1 percent).

## POLE-AND-LINE OBSERVER DATA

## Sources of Data

The pole-and-line observer data held by the OFP were obtained from the observer programme of Solomon Islands and cover 1998 only. The data cover 86 days that were fished or searched; however, 16 days cannot be used because bycatches were not monitored by the observer during the trip. The 70 days that remain were obtained from 22 trips aboard 17 vessels, all of which were flagged in Solomon Islands.

## Species Covered

Tables 9 and 10 presents the number of individuals and tonnage of the following species groups that were observed in the catch: tunas, tuna-like species, sharks and rays, and other fish. Tunas accounted for 99.3 percent of the catch in weight, while non-target species accounted for 0.7 percent. Skipjack, yellowfin and bigeye accounted for 90.0 percent, 9.2 percent and 0.2 percent of the total catch respectively.

The largest catches of non-target species were of rainbow runner (Elagatis bipinnulata) (1.9 t) and mahi mahi (Coryphaena hippurus) ( 1.0 t ). Small numbers of kawakawa (Euthynnus affinus) ( 0.5 t ) and sharks and rays $(0.4 \mathrm{t})$ were also taken.

## School Association

The observed catches by species group are broken down by six categories of school association in Table 11. The largest proportion of the catch was from schools associated with 'anchored raft, FAD or payao' ( 68.0 percent), followed by 'feeding on baitfish' ( 15.5 percent), 'unassociated' (8.7 percent), 'drifting raft, FAD or payao' (3.5 percent) and 'drifting log, debris or dead animal' (1.3 percent). Tuna accounted for over 99 percent of the catch in all categories except 'unassociated' (97.9 percent).

## Species Identification

All observed catches were identified to the species level except for 34 sharks, which represent 18.9 percent of all sharks and rays.

## Discard Rate

Data on discards were not recorded during observer trips aboard the Solomon Islands pole-and-line vessels in 1998. However, comments in the observers' trip narratives suggest that all tuna were retained, while mahi mahi, rainbow runner and kawakawa were retained for crew consumption or trade and all sharks were discarded.

## Geographic Coverage

The geographic coverage of the observed pole-and-line effort is compared to the total pole-and-line effort in the WCPO during 1998 in Figures 5 and 6. The observed pole-and-line effort covers only the waters of Solomon Islands. The pole-and-line fleets of Fiji and and French Polynesia, which fish in the waters of those countries, and the Japanese fleet, which operates in the waters of Japan and several other coastal states, as well as on the high seas, are not covered by observer data.

## Total Coverage and Coverage

Total coverage of the pole-and-line catch of skipjack, yellowfin and bigeye in the WCPO during 1998 is 0.2 percent (Table 12). Coverage for the Solomon Islands fleet is 2.1 percent, while the coverage for all other fleets is zero.

## PURSE-SEINE OBSERVER DATA

## Sources of Data

The purse-seine observer data held by the OFP were obtained from seven observer programmes, i.e. the national programmes of the Federated States of Micronesia (1994-1999), Nauru (1996), Papua New Guinea (1996-1999) and Solomon Islands (1998-1999), and the regional programmes of the FSM Arrangement (1998-2000), SPC (1995-2000) and the US treaty (1994-2000). The US Treaty data account for 66.6 percent of the data, while the national programmes account for 24.6 percent and the other regional programmes account for 8.8 percent (Table 13).

There were 13,068 purse-seine sets made in the WCPO, from 1994 to 2000, that were covered by observer data held by the OFP. However, 3,073 sets cannot be used because bycatches were not monitored by the observer during the trip. An additional 3,415 sets resulted in no catch. The total number of positive sets available for the analysis of bycatch was therefore 6,580 . There were 2,483 sets for which only bigeye, skipjack or yellowfin were caught, leaving 4,097 sets ( 62.3 percent of positive sets) from which non-target species were caught.

## Species Covered

Tables 14 and 15 presents the number of individuals and tonnage of the following species groups that were observed in the catch: tunas, tuna-like species, billfish, sharks and rays, other fish, cephalopods, marine reptiles, and marine mammals. The target species - bigeye, skipjack and yellowfin - accounted for 99.2 percent of the catch in weight, while non-target species accounted for 0.8 percent.

The largest catches of non-target species groups was of other fish ( $1,144 \mathrm{t}$ or 0.43 percent of the total catch), followed by sharks and rays ( 518 t or 0.19 percent). The largest catch of non-target species was of rainbow runner (Elagatis bipinnulata) ( 697 t ) and mahi mahi (Coryphaena hippurus) (124 t). Significant catches of the oceanic triggerfish family (Balistidae) ( 168 t ) were also taken.

## School Association

The number of purse-seine sets observed and observed catches by species group are broken down by eight categories of school association in Tables 16 and 17 respectively. The most common category of school association was 'drifting raft, FAD or payao' ( 34.1 percent), followed by 'feeding on baitfish' (22.0 percent), 'drifting log, debris or dead animal' (21.1 percent) and 'unassociated' (12.4 percent). Tuna accounted for over 99 percent of the catch in all categories except 'drifting log, debris or dead animal' ( 98.3 percent) and 'live whale shark' ( 96.5 percent).

## Species Identification

Table 18 presents the percentage of observed individuals that were not identified to the species level. The percentage is low for tuna ( 0.5 percent) and billfish ( 1.8 percent), whereas it is moderate for other fish ( 16.8 percent) and high for tuna-like species ( 46.0 percent), marine reptiles ( 64.3 percent) and marine mammals ( 100.0 percent).

Most of the unidentified tuna-like species ( 98.1 percent) were species of mackerel. Most of the unidentified sharks and rays ( 97.4 percent) were not identified to the family level. The unidentified 'other fish' consisted primarily of oceanic triggerfish ( 86.6 percent), barracudas ( 7.0 percent) and species of Decapturus (4.4 percent).

## Discard Rate

Table 19 presents the tonnage or number of fish observed, and the tonnage or number retained and discarded, by species group. Only 4.1 percent of the catch of tunas were discarded, whereas 86.2 percent of tuna-like species, 67.7 percent of billfish, 96.3 percent of sharks and rays, and 88.7 percent of other fish were discarded.

## Geographic Coverage

The geographic coverage of the observed purse-seine effort is compared to the total purse-seine effort in the WCPO during 1994-1999 in Figures 7 and 8. The distribution of the observed purse-
seine effort is representative of the total effort, except for the waters of Japan, Indonesia and the Philippines, for which no observer data are available.

## Temporal Coverage

The temporal distribution of observer coverage is presented in Tables 20 and Figures 9 and 10. The total number of sets observed reached a maximum in 1998. The number of sets observed declined in 1999 and 2000 due to a drop in the coverage of the fleets of Japan, Korea and Taiwan.

Coverage as a percentage of the total catch increased from 1.9 percent in 1994 to over 5.0 percent percent during 1996-1998 and then declined.

## Total Coverage and Coverage by Fishing Nation

Total coverage of the catch of target species in the WCPO from 1994, the first year for which purseseine observer data are available, to 2000 is 3.9 percent (Table 20). The level of observer coverage is variable among fleets and years, although coverage is usually less than 5 percent, except for the United States fleet, for which coverage has ranged from 7.4 percent (1994) to 20.5 percent (1997). Excluding the United States fleet, the coverage of the catch of target species in the WCPO from 1994 to 2000 is 1.4 percent.

Table 21 compares the observed catch to the total catch of target species, during 1994-2000, for each fishing nation. The distribution of observer coverage by fishing nation is different from the distribution of the total catch because of the relatively high level of coverage of the United States fleet, which caught 71.6 percent of the observed catch, but only 18.6 percent of the total catch. The percentages of the observed catch represented by Japan, Korea and Taiwan are therefore much lower than the percentages of the total catch. It is notable that the Philippines represents 10.3 percent of the total catch, but only 1.4 percent of the observed catch.

The largest proportion of the observed catch is for the United States fleet ( 71.6 percent), followed by the fleets of Taiwan ( 11.6 percent), Korea ( 7.7 percent), Japan ( 3.5 percent), Philippines (1.4 percent), Federated States of Micronesia (1.0 percent) and Papua New Guinea (1.0 percent).

Table 7. Coverage of longliners in the WCPO by observer data held by SPC. The observed catch (tonnes) and the WCPO catch (tonnes) include albacore, bigeye, skipjack and yellowfin. Estimates of the WCPO catch during 1999 were carried over to 2000. The fleets of Kiribati and Marshall Islands, which have operated only intermittently, have been ignored.
